

## TECHNICAL REFERENCE DOCUMENT: DESIGN & APPLICATION GUIDELINES

### OPERATING INFORMATION: COMMON FEATURES

The features listed in the following pages are common to DC/DC converters.

#### Turn on and off input voltage

The product monitors the input voltage and will turn on and turn off at configured thresholds (see *Technical Specification: part 1 - Electrical Specification*). The turn-on input voltage threshold is set higher than the corresponding turn-off threshold. Hence, there is a hysteresis between turn-on and turn-off input voltage levels.

#### Input voltage transient

The end-user must secure that the transient voltage will not exceed the value stated in the Technical Specification under Absolute maximum ratings of each product. ETSI TR 100 283 examines the parameters of DC distribution networks and provides guidelines for controlling the transient and reduce its harmful effect.

#### Remote control (RC)

The products are fitted with a remote control function referenced to the primary negative input connection (-In), with negative logic options available. The RC function allows the product to be turned on/off by an external device like a semiconductor or mechanical switch. The RC pin has an internal pull up resistor.

The external device must provide a minimum required sink current  $>0.5$  mA to guarantee a voltage not higher than maximum voltage on the RC pin (see Electrical characteristics table). To turn off the product the RC pin should be left open for a minimum time of 150  $\mu$ s, the same time requirement applies when the product shall turn on. When the RC pin is left open, the voltage generated on the RC pin is max 5 V. The standard product is provided with "negative logic" RC and will be off until the RC pin is connected to the -In. To turn off the product the RC pin should be left open. In situations where it is desired to have the product to power up automatically without the need for control signals or a switch, the RC pin shall be wired directly to -In.

Remote control

## Input and output impedance

The impedance of both the input source and the load will interact with the impedance of the product. It is important that the input source has low characteristic impedance. Minimum recommended external input capacitance is given in the *Technical Specification*. Electrolytic capacitors will be degraded in low temperature. The needed input capacitance in low temperature should be equivalent to the value stated in the *Technical Specification* at 25°C. The performance in some applications can be enhanced by addition of external capacitance as described under External decoupling capacitors (next paragraph). If the input voltage source contains significant inductance, the addition of a low ESR ceramic capacitor of 22 – 100 µF capacitor across the input of the product will ensure stable operation. The minimum required capacitance value depends on the output power and the input voltage. The higher output power the higher input capacitance is needed.

## External decoupling capacitors

When powering loads with significant dynamic current requirements, the voltage regulation at the point of load can be improved by addition of decoupling capacitors at the load.

The most effective technique is to locate low ESR ceramic and electrolytic capacitors as close to the load as possible, using several parallel capacitors to lower the effective ESR. The ceramic capacitors will handle high-frequency dynamic load changes while the electrolytic capacitors are used to handle low frequency dynamic load changes. It is equally important to use low resistance and low inductance PWB layouts and cabling.

External decoupling capacitors will become part of the product's control loop. The control loop is optimized for a wide range of external capacitance and the maximum recommended value that could be used without any additional analysis is found in the *Technical Specification* under Electrical specifications. Output filter can be configured and simulated based on the needed control loop and transient response.

For further information please contact your local Flex Power Modules' representative or email us at [pm.info@flex.com](mailto:pm.info@flex.com).

## Output voltage adjust using PMBus

The output voltage of the product can be reconfigured via PMBus command VOUT\_COMMAND (0x21) or VOUT\_TRIM (0x22). This can be used when adjusting the output voltage above or below output voltage initial setting up to a certain level, see Technical Specification for adjustment range.

When changing the output voltage, the voltage at the output pins must be kept within Vtrim max and Vtrim min. Output voltage setting must be kept below the threshold of the over voltage protection (OVP) to prevent the product from shutting down. At increased output voltages the maximum power rating of the product remains the same, and the max output current must be decreased correspondingly.

## Margin up and down control

These controls allow the output voltage to be momentarily adjusted, either up or down, by a nominal 10%. The margin high and margin low shall be limited to max and min output voltage, if the nominal output voltage is changed. This provides a convenient method for dynamically testing the operation of the load circuit over its supply margin or range. It can also be used to verify the function of supply voltage supervisors.

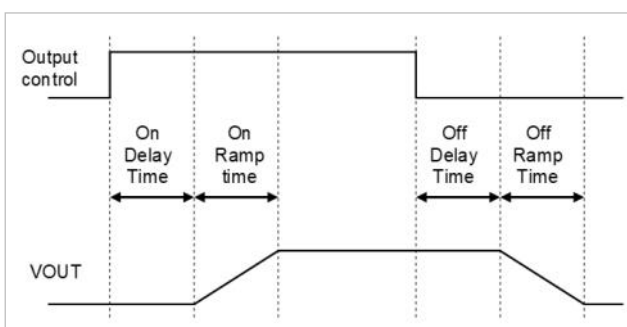

The margin up and down levels of the product can easily be re-configured using [Flex Power Designer software](#).

## Soft start power up and soft stop

The default rise time for a single product is 10 ms. The soft-start and soft-stop control functionality allows the output voltage to ramp-up and ramp-down with defined timing with respect to the control of the output. This can be used to control inrush current and manage supply sequencing of multiple controllers.

The rise time is the time taken for the output to ramp to its target voltage, while the fall time is the time taken for the output to ramp down from its regulation voltage to 0 V. The TON\_DELAY (0x60) sets a delay from when the output is enabled until the output voltage starts to ramp up. When starting by applying input voltage the control circuit boot-up time adds approximately an additional 15 ms delay. The TOFF\_DELAY (0x64) sets a delay from when the output is disabled until the output voltage starts to ramp down.

By default, soft-stop is disabled, and the regulation of output voltage stops immediately when the output is disabled. Soft-stop can be enabled through the PMBus command ON\_OFF\_CONFIG (0x02). The delay and ramp times can be reconfigured using the PMBus commands TON\_DELAY (0x60), TON\_RISE (0x61), TOFF\_DELAY (0x64) and TOFF\_FALL (0x65).

Soft start power up

## Pre-bias start-up

The product has a pre-bias start up functionality and will not sink current during start up if a pre-bias source is present at the output terminals. If the pre-bias voltage is lower than the target value set in VOUT\_COMMAND (0x21), the product will ramp up to the target value. If the pre-bias voltage is higher than the target value set in VOUT\_COMMAND (0x21), the product will ramp down to the target value and in this case sink current for a time interval set by the command TOFF\_MAX\_WARN\_LIMIT (0x66).

## Over/under temperature protection (OTP/UTP)

The products are protected from thermal overload by an internal temperature sensor. The product will make continuous attempts to start up (non-latching mode) and resume normal operation automatically when the temperature has dropped below the temperature threshold set in command OT\_WARN\_LIMIT (0x51). The product also has an under-temperature protection. By default, UTP fault response is set to "Ignore Fault". OTP, UTP, hysteresis and fault responses of the product can be re-configured using Flex Power Designer software.

Note: using the fault response "Ignore Fault" for OTP fault may cause permanent damage to the product.

## Input over/under voltage protection

The product can be protected from high input voltage and low input voltage by a pre-configured value with a response time of 70µs. The over/under-voltage fault level and fault response is easily configured using Flex Power Designer software.

For more information, see *Technical Reference Document: PMBus*.

## Output Over Voltage Protection (OVP)

The product includes over voltage limiting circuitry for protection of the load. If the output voltage exceeds the OVP limit, the product can respond in different ways.

The default response from an over voltage fault is to immediately shut down, with a response time of ~70µs. The device will continuously check for the presence of the fault condition, and when the fault condition no longer exists the device will be re-enabled.

The OVP fault level and fault response can be configured using Flex Power Designer software.

For more information, see *Technical Reference Document: PMBus*.

## Over current protection (OCP)

The products include current limiting circuitry for protection at continuous overload. Standard configuration fault response is set to "disable , do not retry" and it will result in output voltage will shutdown for output currents in excess of max output current (max I<sub>O</sub>). The load distribution should be designed for the maximum output short circuit current specified.

The over current protection and its fault response can be configured using Flex Power Designer software.

For more information, see *Technical Reference Document: PMBus*.

## Switching frequency

The product is optimized at the frequency given in the Technical Specification under part 1- Electrical Specification, but can be set to run at lower or higher frequencies through PMBus configuration. The electrical performance can be affected at different frequencies. Please contact your local Flex Power Modules FAE for more details.

## Multi pin configurations

The MFR\_MULTI\_PIN\_CONFIG (0xF9) command can be re-configured using the PMBus interface to enable or disable different functions and set the pin configuration of the digital header.

The MULTI\_PIN\_CONFIG is easily configured using [Flex Power Designer](#).

For more information, see *Technical Reference Document: PMBus*.

## Address offset

The command FW\_CONFIG\_PMBUS (0xC9) can be configured to utilize different address offset option. There are 3 different address setting option.

1. The bit 16 in command 0xC9 must be set to 1 to enable PMBus address offset via resistors.
2. The resistor address offset in combination with a value set by PMBus base address offset, [31:24] in command FW\_CONFIG\_PMBUS (0xC9). This can be chosen when address resistor is used.
3. A pre-configured PMBus address, [23:17] in FW\_CONFIG\_PMBUS (0xC9). The bit 16 in command 0xC9 must be set to 0 to enable digital PMBus address offset. The digital PMBus address offset in combination with a digital PMBus base address offset, [31:24] in command FW\_CONFIG\_PMBUS (0xC9) adds a larger range of address possibilities. This combination can be chosen if no address resistors are used.

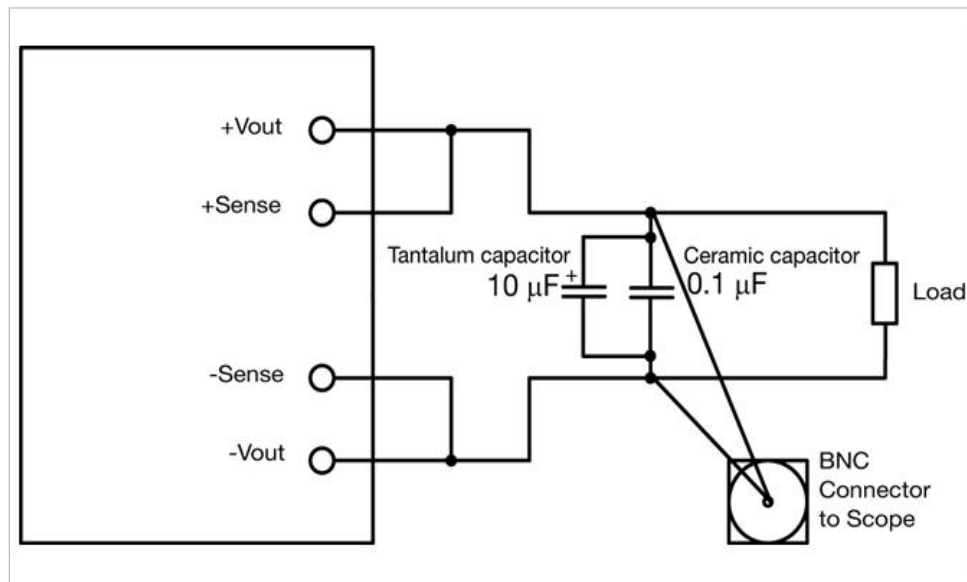

The PMBus-address offset's with resistor value increments the address value following the formula in the PMBus Addressing section of documentation. This increases flexibility when the part is used in single-pin and no-pin addressing scenarios.

## Feed Forward Capability

The BMR351 products have a Feed Forward function implemented that can handle sudden input voltage changes. The output voltage will be regulated during an input transient and will typically stay within 10% when an input transient is applied. The Feed Forward acts on both positive and negative input voltage transients

## Output ripple and noise

Output ripple and noise measured according to figure below.  
See [Design Note 022](#) for detailed information

Output ripple and noise test set-up

## Non-Volatile Memory (NVM)

The product incorporates two Non-Volatile Memory areas for storage of the PMBus command values; the Default NVM and the User NVM. The Default NVM is pre-loaded with Flex factory default values. The Default NVM is write-protected and can be used to restore the Flex factory default values through the command `RESTORE_DEFAULT_ALL (0x12)`.

The User NVM is pre-loaded with Flex factory default values. The User NVM is writable and open for customization. The values in NVM are loaded during initialization according to section Initialization Procedure, where after commands can be changed through the PMBus Interface.

The module contains a one-time programmable memory (OTP) used to store configuration settings, which will not be programmed into the device OTP automatically. The `STORE_USER_ALL(0x15)` commands must be used to commit the current settings are transferred from RAM to OTP as device defaults.

Note: The one-time programmable memory (OTP) has limited storing times, frequent use of `STORE_USER_ALL` command can lead to memory space exhaustion. Remaining available memory is displayed in Flex Power Designer. To retrieve information about OTP memory `MFR_FLEX_FIRMWARE_CMD (0xE0)` can be used, see section OTP Memory Check.

## OPERATING INFORMATION: PRODUCT SPECIFIC FEATURES

### OTP Memory Check

This command, MFR\_FLEX\_FIRMWARE\_CMD (0xE0), can be used to retrieve information about OTP memory. The command works by first writing an 8 byte large block containing instructions for what information to retrieve and then that information is accessed by performing a block read operation. The first 8 bits in the request block contains a sub-command code. The usable codes are described in the following examples:

Read OTP partition size (cmd=0). Retrieves the memory size of a specific partition. This is the size that was set during the OTP partition trim process.

Request:

|        |   |   |   |   |   |   |   |   |               |    |    |        |    |
|--------|---|---|---|---|---|---|---|---|---------------|----|----|--------|----|
| 0      | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |               | 15 | 16 |        | 31 |
| 0      | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | OTP partition |    |    | Unused |    |
| Unused |   |   |   |   |   |   |   |   |               |    |    |        |    |

Response:

|                         |  |  |  |  |  |  |  |  |  |  |  |  |    |
|-------------------------|--|--|--|--|--|--|--|--|--|--|--|--|----|
| 0                       |  |  |  |  |  |  |  |  |  |  |  |  | 31 |
| Partition size in bytes |  |  |  |  |  |  |  |  |  |  |  |  |    |
| Unused                  |  |  |  |  |  |  |  |  |  |  |  |  |    |

Read remaining memory size of OTP partition (cmd=1). Retrieves the remaining memory size of a specific partition. This is the size that is still available for writing patches, which depending on the partition can be firmware patches, PMBus configuration patches or snapshot events.

Request:

|        |   |   |   |   |   |   |   |   |               |    |    |        |    |
|--------|---|---|---|---|---|---|---|---|---------------|----|----|--------|----|
| 0      | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |               | 15 | 16 |        | 31 |
| 1      | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | OTP partition |    |    | Unused |    |
| Unused |   |   |   |   |   |   |   |   |               |    |    |        |    |

Response:

|                         |  |  |  |  |  |  |  |  |  |  |  |  |    |
|-------------------------|--|--|--|--|--|--|--|--|--|--|--|--|----|
| 0                       |  |  |  |  |  |  |  |  |  |  |  |  | 31 |
| Remaining size in bytes |  |  |  |  |  |  |  |  |  |  |  |  |    |
| Unused                  |  |  |  |  |  |  |  |  |  |  |  |  |    |

Read size of STORE\_X\_ALL memory usage (cmd=2). Retrieves the memory used when storing a full PMBus configuration through STORE\_DEFAULT\_ALL or STORE\_USER\_ALL. This includes padding bytes for alignment, the OTP frame size and checksum.

Request:

|        |   |   |   |   |   |   |   |   |               |    |    |        |    |

|---------------------|--|--|--|--|--|--|--|--|--|--|--|--|----|
| 0                   |  |  |  |  |  |  |  |  |  |  |  |  | 31 |
| Block size in bytes |  |  |  |  |  |  |  |  |  |  |  |  |    |
| Unused              |  |  |  |  |  |  |  |  |  |  |  |  |    |

## Power good

The power good pin (PG) indicates when the product is ready to provide regulated output voltage to the load. During ramp-up or during a fault condition, PG is held low. By default, PG is asserted high after the output has ramped past limit set by POWER\_GOOD\_ON (0x5E), and de-asserted if the output voltage falls below limit set by POWER\_GOOD\_OFF (0x5F). These thresholds can be re-configured using Flex Power Designer software.

By default, the PG pin is configured as open drain output, but it is also possible to set the output in push/pull mode by the command MFR\_MULTI\_PIN\_CONFIG (0xF9).

The polarity is by default configured to active high, the polarity of PG can be set to active high using bit [39] in the command FW\_CONFIG\_PMBUS (0xC9) :

bit[39] = 0 (active low)

bit[39] = 1 (active high)

The product provides a Power Good flag in the Status Word register that indicates the output voltage is within a specified tolerance of its target level and no-fault condition exists. It is not recommended to use push-pull when paralleling PG- pins.

For more information, see *Technical Reference Document: PMBus*.

## Remote Control (secondary side)

The Power Good pin (Pin 8) can be configured as a remote control pin with a combination of hardware and PMBus configuration. With hardware option, Pin 8 used for secondary remote control, Power Good is disabled. The secondary remote control uses an internal pull-up resistor. The logic options for the secondary remote control can be positive or negative logic. The logic option for the secondary remote control is easily configured via ON\_OFF\_CONFIG (0x02) using Flex Power Designer software command.

## Parallel operation Active Current Sharing (ACS)

Two or more products may be paralleled for redundancy if the total power is equal or less than  $P_{O\max}$ . The products provide output voltage droop corresponding to pre-configured artificial resistance in the output circuit to enable direct paralleling. The stated output voltage set point is at no load. The output voltage will decrease when the load current is increased. This feature allows the products to be connected in parallel and share the current. To prevent unnecessary current stress, changes of the output voltage must be done with the output disabled. This must be considered for all commands that affect the output voltage.

Each module in the bus will trim its regulated output up and down continuously to be able to output the same current seen from the current share bus. This feature will cancel out the current share error caused by the modules output voltage deviation, temperature deviation and layout asymmetry. The max load of the paralleled modules equals to (max load of single module-7A) \* number of paralleled modules. The 7A is the maximum error of the output current monitor and current accuracy between products in a current sharing group is  $2 \times 7A$ . The modules are adjusting their output continuously according to the ACS algorithm, the output voltage at idle will vary maximum  $\pm 100mV$  due to limitations in idle current measurements. The maximum load during ramp up will be limited to number of modules  $\times$  nom load of single module  $\times 90\%$  ( $n_{\text{modules}} \times I_{\text{outnom}} \times 0.9$ ).

How to setup the ACS: All the IMON (Pin 14) pins of the paralleled modules need to be tied together and close to each module.

## Peak power / Slow OCP

In order to handle higher power than the thermal design power (TDP), the DC/DC converter uses a peak power calculation function. It is build upon a Exponential Moving Average (EMA) method, weighting new current measurements against old current measurements. At all times when telemetry is active, the instantaneous output current will be added to the average output current using EMA. A fault limit can be configured to compare against the averaged value and trigger the over current fault response when exceeded. Peak power is configured to allow a load step from TDP to Peak Power level for 70ms. Even higher power can be achieved but for a decreased time period. See technical specification for Slow OCP configuration limits.

High  $di/dt$  on load step up to peak power, might cause current overshoot resulting in OCP fault. Maximum load step slew rate is application dependent and can vary between systems. Application test is required to find maximum load step slew rate.

For further assistance, contact your local Flex Power Modules' representative or email us to [pm.support@flex.com](mailto:pm.support@flex.com)

## POWER MANAGEMENT

### PMBUS overview

This product is equipped with a PMBus interface. The product incorporates a wide range of readable and configurable power management features that are simple to implement with a minimum of external components. Additionally, the product includes protection features that continuously safeguard the load from damage due to unexpected system faults. A fault is also shown as an alert on the SALERT pin. The following product parameters can continuously be monitored by a host: Input voltage, output voltage/current, duty cycle and internal temperature.

The product is delivered with a default configuration suitable for a wide range operation in terms of input voltage, output voltage, and load. The configuration is stored in an internal Non-Volatile Memory (NVM). All power management functions can be reconfigured using the PMBus interface.

Throughout this document, different PMBus commands are referenced. The Flex Power Designer software suite can be used to configure and monitor this product via the PMBus interface. More information is found on [our website](#).

### SMBus interface

This product provides a PMBus digital interface that enables the user to configure many aspects of the device operation as well as to monitor the input and output voltages, output current and device temperature. The product can be used with any standard two-wire I<sup>2</sup>C (master must allow for clock stretching) or SMBus host device. In addition, the product is compatible with PMBus version 1.3 and includes an SALERT line to help mitigate bandwidth limitations related to continuous fault monitoring. The product supports 100 kHz and 400 kHz bus clock frequency only. The PMBus signals, SCL, SDA and SALERT require passive pull-up resistors as stated in the SMBus Specification. Pull-up resistors are required to guarantee the rise time as follows:

$$\tau = R_p C_p \leq 1\mu s$$

where  $R_p$  is the pull-up resistor value and  $C_p$  is the bus load. The maximum allowed bus load is 400 pF. The pull-up resistor should be tied to an external supply between 2.7 to 3.8 V, which should be present prior to or during power-up. If the proper power supply is not available, voltage dividers may be applied. Note that in this case, the resistance in the equation above corresponds to parallel connection of the resistors forming the voltage divider.

It is recommended to always use PEC (Packet Error Check) when communicating via PMBus.

### PMBus addressing

The following figure and table show recommended resistor values with min and max voltage range for hard-wiring PMBus addresses (series E96, 1% tolerance resistors suggested):

Schematic of connection address resistors

| SA1 index | R <sub>SA1</sub> [kΩ] | Resulting address with MFR_OFFSET_ADDRESS = 0x60 |
|-----------|-----------------------|--|
| 0         | 10                    | 96d (0x60)                                       |
| 1         | 15                    | 97d (0x61)                                       |
| 2         | 21                    | 98d (0x62)                                       |
| 3         | 28                    | 99d (0x63)                                       |
| 4         | 35.7                  | 100d (0x64)                                      |
| 5         | 45.3                  | 101d (0x65)                                      |
| 6         | 56.2                  | 102d (0x66)                                      |

| SA1 index | R <sub>SA1</sub> [kΩ] | Resulting address with MFR_OFFSET_ADDRESS = 0x60 |
|-----------|-----------------------|--|
| 7         | 69.8                  | 103d (0x67)                                      |
| 8         | 88.7                  | 104d (0x68)                                      |
| 9         | 107                   | 105d (0x69)                                      |
|           |                       |  |
|           |                       |  |
|           |                       |  |
|           |                       |  |

PMBus base address offset value is configured via PMBus command 0xC9. Specific variants may already have a default non-zero value set for PMBus base address offset.

Configuring the address setup by command FW\_CONFIG\_PMBUS (0xC9), see section Offset Address.

The allowed range of the PMBus address is: 1-126 excluding 12 and 16. When the calculated PMBus address falls outside the allowed range address 126 is assigned instead. It is not recommended to keep the SA1 pins left open.

## I2C/SMBus timing

The setup time,  $t_{\text{set}}$ , is the time data, SDA, must be stable before the rising edge of the clock signal, SCL. The hold time  $t_{\text{hold}}$ , is the time data, SDA, must be stable after the rising edge of the clock signal, SCL. If these times are violated incorrect data may be captured or meta-stability may occur and the bus communication may fail. All standard SMBus protocols must be followed, including clock stretching. This product supports the BUSY flag in the status commands to indicate product being too busy for SMBus response. A bus-free time delay between every SMBus transmission (between every stop & start condition) must occur. Refer to the SMBus specification, for SMBus electrical and timing requirements.

Note that an additional delay of 5 ms has to be inserted in case of storing the RAM content into the internal non-volatile memory.

Set-up and hold timing diagramm

## Monitoring via PMBus

It is possible to continuously monitor a wide variety of parameters through the PMBus interface. These include, but are not limited to, the parameters listed in the table below.

| Parameter           | PMBus command      |
|---------------------|--------------------|
| Input voltage       | READ_VIN           |
| Output voltage      | READ_VOUT          |
| Output current      | READ_IOUT          |
| Temperature*        | READ_TEMPERATURE_1 |
| Switching frequency | READ_FREQUENCY     |
| Duty cycle          | READ_DUTY_CYCLE    |

\* reports the temperature from temperature sensor set in command 0xDC, internal (controller IC)/external (temp. sensor)

## Monitoring faults

Fault conditions can be detected using the SALERT pin, which will be asserted low when any number of pre-configured fault or warning conditions occurs. The SALERT pin will be held low until faults and/or warnings are cleared by the CLEAR\_FAULTS command, or until the output voltage has been re-enabled. It is possible to mask which fault conditions should not assert the SALERT pin by the command SMBALERT\_MASK. In response to the SALERT signal, the user may read a number of status commands to find out what fault or warning condition occurred, see table below.

| Fault and warning status | PMBus command              |
|--------------------------|----------------------------|
| Overview, Power Good     | STATUS_BYTE<br>STATUS_WORD |

## BLACK BOX/EVENT READER

### Overview

A black box, or history event recorder, is provided to capture brick data at the time of fault occurrence. The intent is to assist in fault diagnosis.

Black box will respond to following faults: OVF (output), OCF, OTF. For each fault a block of data will be stored into a dedicated black box memory partition. This partition consists of 4KiB non-volatile memory and can store a total of 102 events. When the memory section for event recording is filled up, no more black box data can be stored.

When a fault occurs, the following data will be stored:

- Telemetry for Vin, Vout, Iout, temperature and duty
- All PMBus status registers
- Regulation state of module, current and prior to fault.
- Time stamp

If several subsequent faults of the same type occur only the first fault of same type will be recorded. Though, if fault is cleared e.g. with RC or PMBus a new fault of same type will activate a new recording.

All telemetry values are two's complement numbers:

| Telemetry      | #bits | LSB               |
|----------------|-------|-------------------|
| Input voltage  | 16    | 125 mV            |
| Output voltage | 16    | 488.28125 $\mu$ V |
| Output current | 16    | 1 A               |
| Temperature    | 16    | 1 °C              |
| Duty           | 16    | 1 %               |

The PMBus status registers have the same form as their corresponding PMBus registers. See section 17 of PMBus specification part II rev 1.3 for details.

Regulation states upper 4 bits represent state prior to fault. Lower 4 bits represent current state.

| No. | State:     |
|-----|------------|
| 0   | IDLE       |
| 1   | TON_DELAY  |
| 2   | RAMP UP    |
| 3   | REGULATING |
| 4   | TOFF_DELAY |
| 5   | RAMP DOWN  |
| 6   | FAULT      |

## Black box/event reader

Time stamp:

| Name     | #bits | LSB             |
|----------|-------|-----------------|
| ticks_hi | 8     | ~1563.75 h      |
| ticks    | 32    | 1310.72 $\mu$ s |

Max: ~45years. Note, due to Non-Volatile memory, ticks counter will restart at 0 each time power is cycled.

### Method of retrieving event data

1. Read the number of total events by performing a **Read Word** on 0xDB (MFR\_EVENT\_INDEX). The index of the first event is 0 and the index of the last event is *number of total events - 1*.
2. Set the current index by performing a **Write Word** on 0xDB (MFR\_EVENT\_INDEX).
3. Read the event data by performing a **Block Read** on 0xD7 (MFR\_READ\_EVENT). The format of the response data can be seen in the table below.
4. Unless done, choose a new index and continue from **2**.

READ\_EVENT response (Block Read 0xD7, 26 bytes):

| 0                |           | 7 | 8                  | 15 | 16               | 23 | 24           | 31 |
|------------------|-----------|---|--------------------|----|------------------|----|--------------|----|
| Index            |           |   |                    |    | V <sub>in</sub>  |    |              |    |
| V <sub>out</sub> |           |   |                    |    | I <sub>out</sub> |    |              |    |
| Temperature      |           |   |                    |    | Duty             |    |              |    |
| STATUS_WORD      |           |   |                    |    | STATUS_VOUT      |    | STATUS_IOUT  |    |
| STATUS_INPUT     |           |   | STATUS_TEMPERATURE |    | STATUS_CML       |    | STATUS_MFR   |    |
| Error state      | Old state |   | Ticks byte 4       |    | Ticks byte 0     |    | Ticks byte 1 |    |
| Ticks byte 2     |           |   | Ticks byte 3       |    |                  |    |              |    |
