DESCRIPTION
THERMAL MODEL FOR
PKB4413D PIHS

FLEX POWER MODULES

Contents

General

The model is based on and valid for PKB4413D PIHS which is a through hole pin design. The model is intended for steady-state thermal simulations.

Model Description

The model is a readymade Flotherm 11.1 model. It was created by importing a CAD model in STEP format through the MCAD bridge. Components that are not contributing to the heat transfer, have been removed from the geometry.

The model consists of the four major components:

3D CAD Geometry

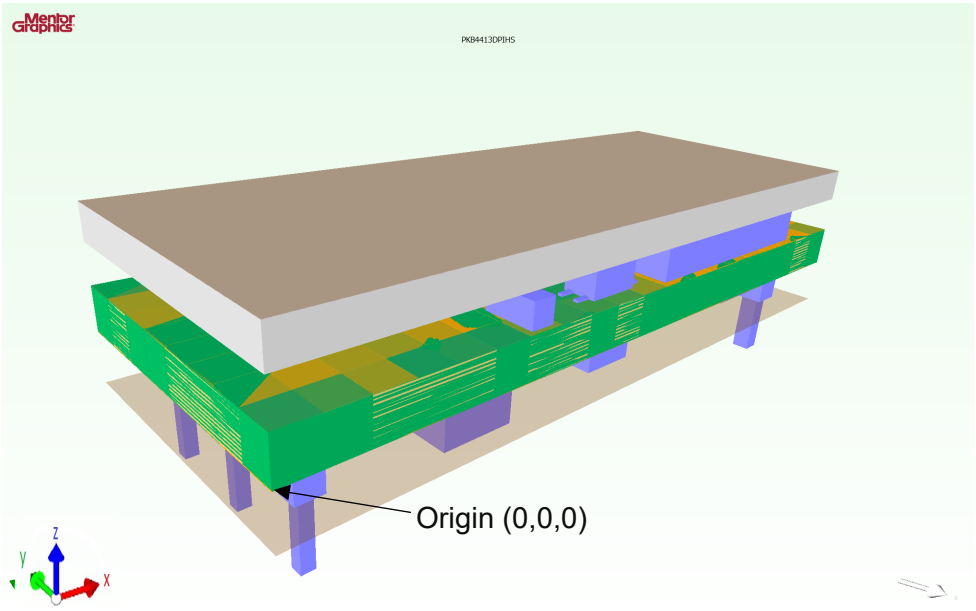

Figure 1. Model origin in lower left corner of the PCB and axis orientation

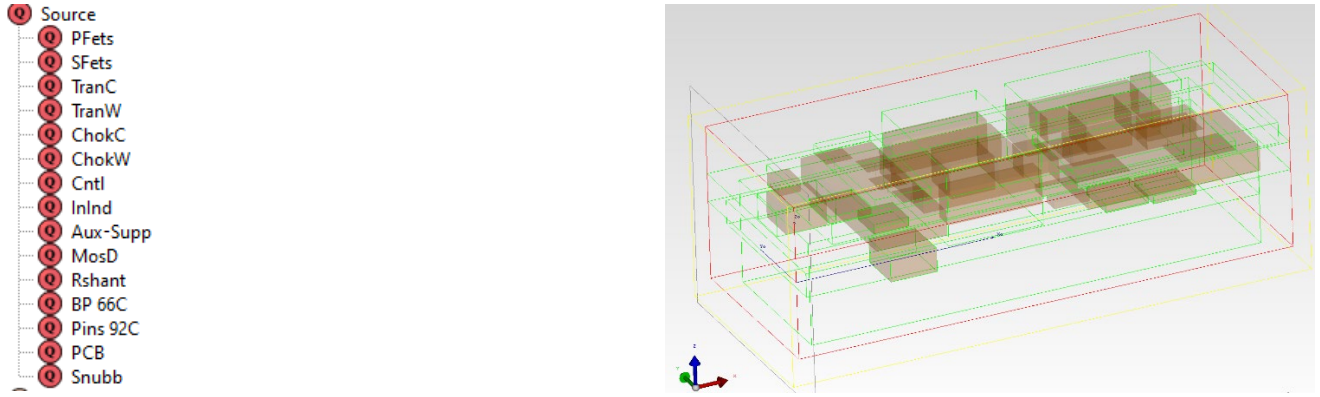
3D geometry is created by importing a CAD model in STEP format through the MCAD bridge. Components that are not contributing to the heat transfer have been removed from the geometry. The PCB has been imported through FloEDA bridge module. The level of modeling is detailed one which means each layer has its own material properties based on the layer copper coverage. This detailed level includes also dielectric layers and vias.

Origin has been placed so that [0,0,0] is in the lower left corner of the PCB. Unit in file: [mm]

Domains of power loss distribution

There are several sources for power loss. The power loss for each of them, at certain module total powers, are given in *Appendix 1 - Power Loss Distribution*



(a) (b)

Figure 2. Power loss setting: (a) list of heat sources, and (b) heat sources distribution over the model

Domains of material data

There are several material domains. The heat conductivity for each of them is given either as isotropic, or anisotropic values in x-,y-, and z-direction (x,y,z) per the following list.

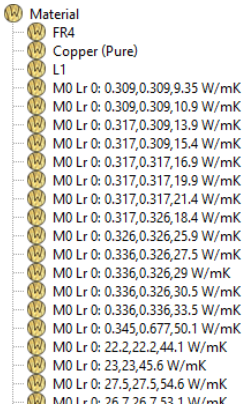


Figure 3. Domains of material data

Note. The given heat conductivities are only intended to model the temperature distribution of the module in this application. The values should not be treated as physically true or transferable to other applications.

Monitor points

Monitor points are set according to the thermal verification report of this product. Figure 4 shows the top and pin sides and the location of the thermo-couples.

Model Calibration

The model has been calibrated to give temperatures as similar as possible compared to measured temperatures reported in the product's thermal verification report for 53V Vin, 12V Vout and 37.5A Iout. In these calculations, temperature of the application board is set to 92℃ and temperature of the baseplate (at top end) is set to 66. Conduction heat transfer is only considered here which means heat does not transfer to the surrounding air.

Flotherm simulation temperatures are within ±5℃ compared to results from measurements (Figure 5).

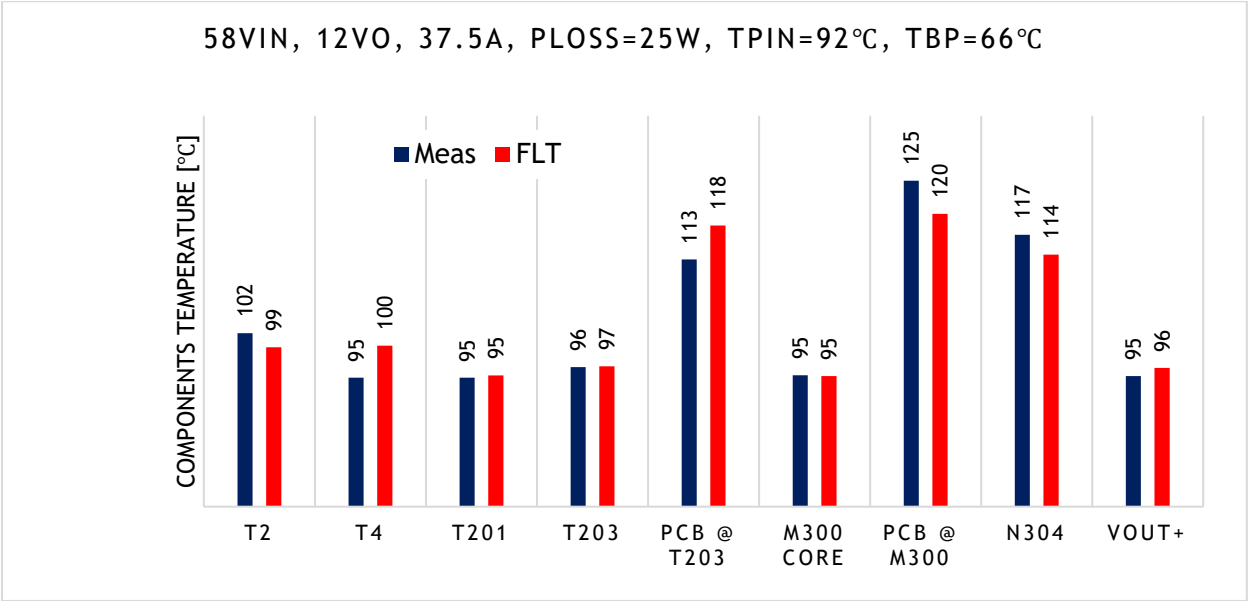

Figure 5. Model calibration result- FLT: Flotherm simulation results, and Meas: Measured temepratures reported in the thermal report.

Model Usage

Import the *.pdml file into the desired project.

Adjust the dissipated power by altering the thermal heat sources in Figure 2, according to Appendix 1 - Power Loss Distribution. Default settings are for 25.27[W].

Note1: If the model is rotated, make sure that the orientation of the orthotropic materials properties is preserved (also rotated).

Note2: Do not change the order of power sources and geometry objects, as this can change the power and material settings.

The module temperatures can be monitored in predefined monitor points.

Additional Information

Model has been constructed with SI units.

Disclaimer

The model and model documentation described herein are provided for the sole purpose of facilitating thermal modeling of a structure where the referenced product is included. It should not and cannot be interpreted neither as a detailed description of the product itself, nor as a statement of the product's performance.

The model has been constructed on a best effort basis, but we cannot accept liability for any discrepancy between model predictions and actual values.
